Nuclear medicine is a specialized area of radiology that uses very small amounts of radioactive substances to examine organ function and structure. It can also be used as a therapeutic approach to treat certain diseases. Nuclear medicine scans provide information about various organ functions by imaging the concentration of specially formulated radioactive chemical compounds in selected parts of the body.

Therapeutic radiology is also called radiation oncology or radiation therapy. It is the treatment of cancer and other diseases with radiation. Oncology is the branch of medicine that focuses on diagnosing and treating cancer. Radiation in many forms is used to kill the cancer cells by preventing them from multiplying.

Nuclear medicine imaging uses small amounts of radioactive materials called radiotracers that are typically injected into the bloodstream, inhaled or swallowed. The radiotracer travels through the area being examined and gives off energy in the form of gamma rays which are detected by a special camera and a computer to create images of the inside of your body.

Nuclear medical imaging is one approach for seeing what X-rays cannot reveal. Nuclear medicine technologists administer drugs with small amounts of radioactive materials to patients. These substances give off a form of radiation that can be picked up by specialized imaging equipment, giving doctors a clearer view of what is going on in organs and other soft tissues.

### **Nuclear engineering - Wikipedia**

Nuclear medicine is a medical specialty involving the application of radioactive substances in the diagnosis and treatment of disease. Nuclear medicine imaging, in a sense, is "radiology done inside out" or "endoradiology" because it records radiation emitting from within the body rather than radiation that is generated by external sources like X-rays. In addition, nuclear medicine scans differ from radiology, as the emphasis is not on imaging anatomy, but on the function.
