Tower Of Hanoi Big O

The 3-peg Tower of Hanoi problem is known to require 2^{n-1} steps for moving n discs with distinct radii from one tower to another tower by following the rule that a larger disc may never be placed on top of a smaller disc, using a third tower as intermediate storage. This number of steps has been proven to be optimal.

The Tower of Hanoi is a mathematical game or puzzle. It consists of three rods and a number of disks of different sizes, which can slide onto any rod. The puzzle starts with the disks in a neat stack in ascending order of size on one rod, the smallest at the top, thus making a conical shape. The objective of the puzzle is to move the entire stack to another rod, obeying the following simple rules: Only one disk can be moved at a time. Each move consists of taking the upper disk from one of the s

Before getting started, let's talk about what the Tower of Hanoi problem is. Well, this is a fun puzzle game where the objective is to move an entire stack of disks from the source position to another position. Three simple rules are followed: 1. Only one disk can be moved at a time. 2. Each move consists of taking the upper disk from one of the stacks and placing it on top of another stack.

The Tower of Hanoi problem with 3 pegs and n disks takes $2^{**n} - 1$ moves to solve, so if you want to enumerate the moves, you obviously can't do better than $O(2^{**n})$ since enumerating k things is $O(k)$. On the other hand, if you just want to know the number of moves required (without enumerating them), calculating $2^{**n} - 1$ is a much faster operation.

Big-O Analysis of Algorithms. The Big O notation defines an upper bound of an algorithm, it bounds a function only from above. For example, consider the case of Insertion Sort. It takes linear time in best case and quadratic time in worst case. We can safely say that the time complexity of Insertion sort is $O(n^2)$.
